

International Conference on**DENTAL MEDICINE, TRAUMA AND RECONSTRUCTIVE SURGERY****September 10-11, 2018 Singapore****Immediate implant placement in fresh extraction socket****Rajat Kr Sachdeva**

Sachdeva's Dental Institute, India

According to Branemark, a two-stage surgery was believed mandatory in order to contribute towards a stress free healing period for the implants to osseointegrate. Also, the original principles stated after tooth extraction it's mandatory to wait for 6-12 months in order to allow complete healing of alveolar bone. However, during the healing period, a considerable amount of alveolar bone can be lost as a result of bone resorption. Certainly, with series of advances in the implant dentistry in past decades has led to alterations in the original protocol. Immediate implant placement in a fresh extraction socket has been signified to accomplish a desired result i.e. prevention of bone resorption. Immediate implant placement in fresh extraction socket prevent undue resorption tend to occur post extraction and maintenance of gingival form and interdental papilla.
