Gomal University, Pakistan

The Epstein-Barr virus (EBV) is a *herpesvirus* infecting more than 90% of the human population. The tropism of EBV for B lymphocytes is evidenced in its association with many *lymphoproliferative disorders*. Different types of EBV (EBV-1 and EBV-2), classified based on EBNA-2 genotyping, have been reported in benign and malignant pathologies, but there is almost no information about their frequency in the Pakistani population. The aim of this study was to determine the frequency and distribution of EBNA-2-based EBV genotypes in lymphoma patients. Genomic DNA was extracted from formalin-fixed paraffin embedded (FFPE) tissue samples obtained from 73 EBV-DNA-positive lymphoma patients. The  $\beta$ -globin gene was amplified to assess the presence and quality of cellular DNA from all samples. EBER-1 DNA was detected by PCR to confirm EBV presence in tissue samples. EBNA-1 mRNA relative quantification by quantitative PCR substantiated EBNA-1 mRNA overexpression in 43.8% of EBV-positive cases in comparison to an EBV-positive cell line control. EBNA-2 genotyping was done by nested polymerase chain reaction (PCR). Among typable samples, EBV-1 was present in 90.7%; EBV-2, in 9.3%. These results show that EBV-1 is the most prevalent type in the lymphoma population of Pakistan, like reports from other countries. This definition of EBV epidemiology in Pakistani lymphoma patients represents an important first step in using EBV for prognosis and monitoring treatment response in patients.

### Biography

Sadia Salahuddin is a PhD Scholar at Gomal University. She has worked at Cornell University and University of North Carolina as Research Scholar for four years. She has authored number of good quality research articles in reputed journals and has been serving as an Editorial Board Member of reputed journal.
