Short Communication

Cisplatin (CP) is a powerful and dynamic cytostatic drug whose clinical application is limited by its nephrotoxicity. Although CP nephrotoxicity in patients can be monitored through diuretics and hydration regimens, the prevalence of CP nephrotoxicity still occurs in approximately one-third of patients undergoing CP treatment. Experimental animal studies have demonstrated that CP accumulates in the kidney more than other organs and specifically damages the proximal tubules. Human organic cation transporter 2 (hOCT2) is mainly expressed in the basolateral membrane of renal proximal tubule cells [1]. Several *in-vitro* and *in-vivo* studies from 2005 to 2008 confirmed that CP uptake via hOCT2 and rat OCT2 [2-5]. The treatment of wild type animals with CP and cimetidine, a substrate for OCT2 transport, reduced the nephrotoxic effects of CP [6]. Importantly, the administration of cimetidine in patients treated with CP produces nephron-protection effects without compromising the efficacy of CP tumor therapy [7]. Furthermore, another study revealed that hOCT2 genetic polymorphisms in combination with cimetidine protected patients from CP-induced nephrotoxicity [8]. Thus, OCT2 is a critical transporter for CP in the kidney and a promising target to halt the undesirable nephrotoxic effects of CP. The study by Sprowl et al. elucidated that Oct1/2^(-/-) mice were not completely protected from CP-induced tubular necrosis, while the loss of tumor protein p53 in Oct1/2^(-/-) mice conferred complete protection. Clinically, non-competitive inhibitors of OCT2 function and p53 inhibitors such as pifithrin- α abrogated the activation of p53 and cyclin-dependent kinase inhibitor p21 as well as the cleavage of caspase-3 in CP-treated mice [9]. In addition, another study by Wei et al. (2007) showed that the degree of renoprotection conferred by pifithrin- α is significantly higher than that in p53^(-/-) mice receiving cisplatin alone [10]. A careful analysis of the results of two previous studies by Sprowl et al. illustrated that pifithrin- α may be a unique and independent dual OCT2 and p53-inhibitor capable of circumventing the nephrotoxic effects of CP. Interestingly, the abrogation of OCT2 function through the inactivation of the p53 pathway is necessary to offer complete protection from CP-induced nephrotoxicity. Moreover, p53 plays an important role in CP-induced nephrotoxicity independent of OCT2 function [11,12]. In 2013, a study by Nematbakhsh et al. reported that CP-induced nephrotoxicity is gender dependent; they observed a greater intensity of damage in males than in females through an

unknown mechanism [13]. Previously, author suggested this difference may be related to CP uptake by OCT2 because OCT2 renal expression is significantly higher in males than in females. Hence, CP uptake by the kidneys was increased through the over-expression of OCT2 in male rats and was associated with increased CP-induced nephrotoxic effects [14]. Furthermore, author proposed that the main player in the gender differences in OCT2 gene expression in rats is testosterone. This proposal is consistent with the findings of a study that found OCT2 levels to be significantly reduced in mice after castration and another study that indicated that CP therapy should be avoided when serum testosterone levels are high because high levels of testosterone promote CP-induced kidney injury [15]. However, several studies have exhibited contrasting effects of certain natural products or synthetic compounds on CP-induced nephrotoxicity in both sexes by using the same doses and regimens [16-21]. Substantially, a recent study concluded that formononetin, the main compound of herbal isoflavone found in the red clover plant, decreases CP accumulation in the kidney through the down regulation of OCT2 expression. Functionally, several studies have proven that formononetin is a testosterone 5 α -reductase inhibitor. Testosterone is reduced at the 5 α position to its active metabolite, dihydrotestosterone (DHT), by 5 α -reductase. Therefore, author recently claimed that formononetin reduced the expression of OCT2 through the DHT pathway [22]. A recent pioneer work by Hu et al. (2017) revealed that organic anion transporter 1/3 (OAT1/OAT3) is a novel pathway for mercapturic acid metabolite of CP uptake independent of the OCT2 pathway. The existence of a mercapturic acid metabolite of CP called NAC-1, which acts as a progenitor for renal injury through upstream of p53 [23]. The actions of these two transporters can be abrogated by nilotinib, a tyrosine kinase inhibitor without compromising the antitumor effects of CP [23]. Hence, the regulation of these renal transporters represents a new target for treatment of acute renal toxicity. In rats, the male-dominant expression of Oat1/Oat3 is regulated by the transcription factor B Cell CLL/Lymphoma 6 (BCL6) and not affected by testosterone [24]. However, the implication of Oat1/Oat3 in the gender regulation of CP-induced nephrotoxicity in rats remains unanswered. Moreover, the possible regulatory function of BCL6 on gender differences of CP nephrotoxicity still uncovered also (Figure 1). Therefore, further work on the gender regulation of CP uptake by the kidney could reveal new target pathways to improve the current stand of therapeutic index of CP and offer more alternatives for clinicians and patients to promote longer survival and better quality of life.

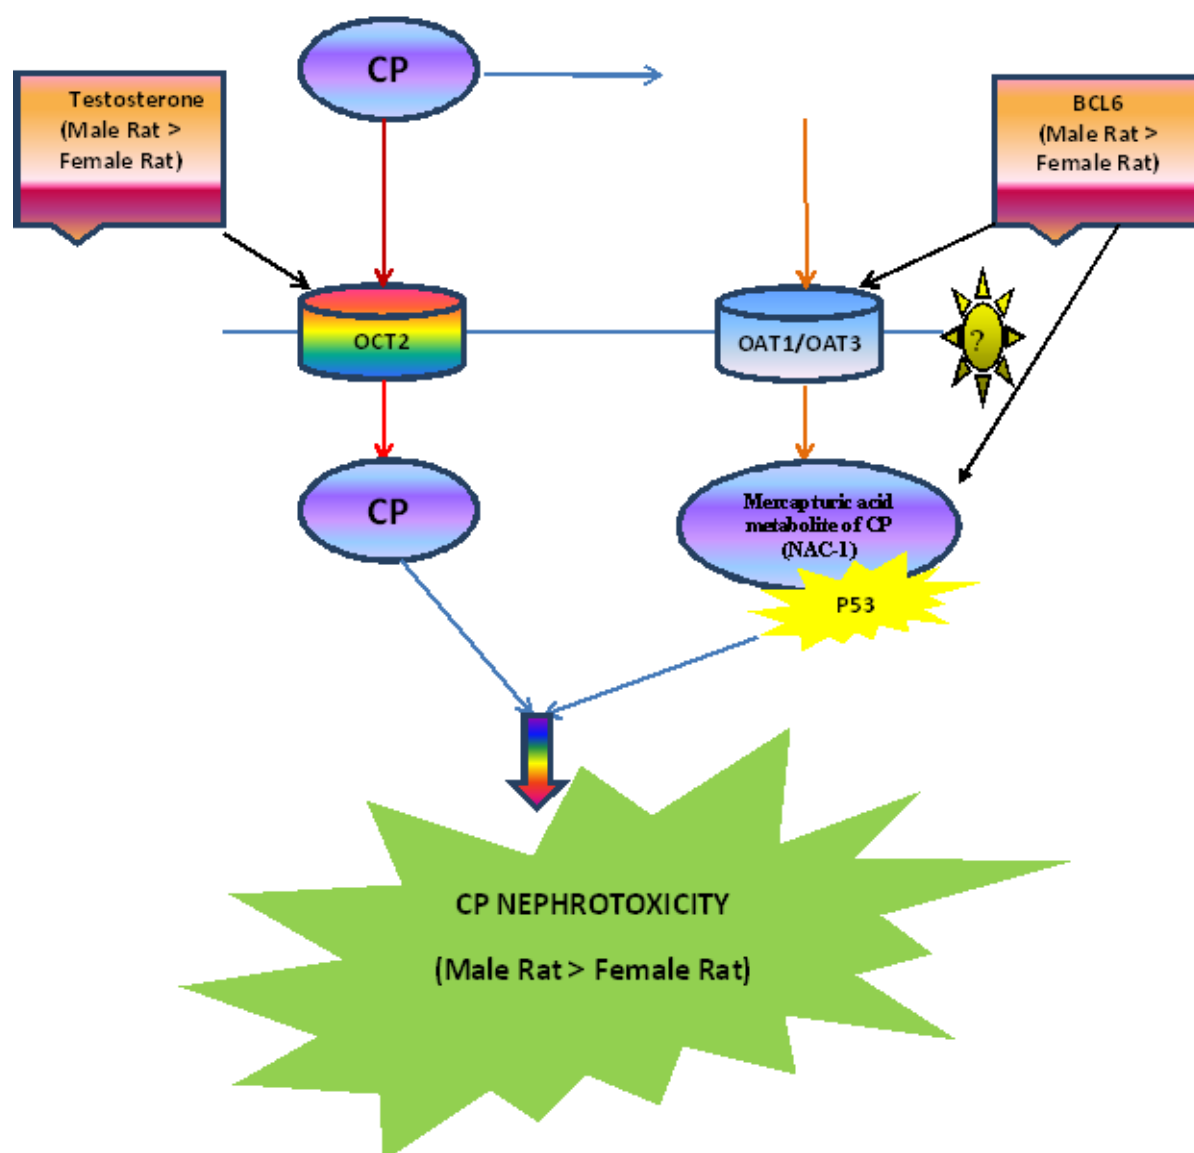

Figure 1: Testosterone is critical player in CP-induced nephrotoxicity through regulation of the OCT2. However, the role of BCL6 in kidney uptake for metabolite of CP remains unanswered.
