Abstract

Objective: To study Matrix Metalloproteinase-3 (MMP-3) and Osteopontin (OPN) levels and correlations of MMP-3 and OPN with Bone Metabolic Markers and Bone Mineral Density (BMD) in postmenopausal Chinese women.

Methods: MMP-3, OPN Osteoprotegrin (OPG), Osteoprotegrin Ligand (OPGL) of 120 postmenopausal Chinese female volunteers was measured using ELISA. BMD were measured using dual energy X-ray absorptiometry. According to the criteria of WHO, women were divided into 3 groups, such as normal, osteopenia and osteoporosis group.

Results: OPN concentrations were significantly higher in osteoporosis (56 ± 20) ng/ml than normal (26 ± 11) ng/ml ($P < 0.05$). But MMP-3 concentrations were little higher in osteoporosis (153 ± 121) ng/ml than normal (125 ± 101) ng/ml.

In osteoporosis, notable negative correlations between OPN, ratio of OPN/MMP-3 and BMD, sOPGL were found ($P < 0.05$) as well as positive relations between OPN, ratio of OPN/MMP-3 and sOPG ($P < 0.05$), and positive relation of MMP-3 and BMD of Ward's triangle was existed ($P < 0.05$), in osteopenia negative relations of MMP-3 and BMD as well as ratio of OPN/MMP-3 were detected ($P < 0.05$). Conclusion: There are significant correlations between serum OPN, ratios of OPN and MMP-3 and bone biomarkers of sOPG, sOPGL, OPN and OPN/MMP-3 may increase with high bone-metabolism. The increases of OPN and ratio of OPN/MMP-3 appear possibly as a concomitant event in high bone turnover state, such as postmenopausal osteoporosis.

Keywords: Matrix metalloproteinase-3; Osteopontin; Bone mineral density Postmenopausal-osteoporosis

Osteoporosis is a metabolic condition characterized by decreased bone mass and strength due to increased bone turnover, which compromises bone architecture and results in increased fracture risk. Postmenopausal osteoporosis is the most common type of osteoporosis associated with estrogen deficiency [1]. However, the mechanisms by which estrogen deficiency causes bone loss are complex and are not fully understood.

Matrix metalloproteinase (Matrix Metalloproteinase, MMP) forms a family of zinc-dependent proteinases essential for several physiological and pathological events, such as embryonic development, angiogenesis, wound repair, periodontal disease, rheumatoid arthritis, cancer invasion, and metastasis. Osteoblast-derived MMPs have been shown to play a role in bone metabolism by degradation of the bone matrix. Bone resorption is dependent on the activity MMP-3, which degrades denatured type II collagen and other components of the bone organic matrix. Evidence has accumulated for an active participation by osteoblast-derived MMPs in the initiation of bone resorption and coupled bone formation by degrading the unmineralized osteoid layer of the bone surface to allow osteoclasts to attach to the mineralized matrix. In vitro [2,3], normal osteoblasts secrete abundant MMP-3 which was triggered by osteopontin (OPN), then OPN-MMP-3 complex were existed to induce bone matrix into ossification before bone mineralization.

Methods

Subjects

The study population comprised 120 postmenopausal women aged 48–65 years, selected randomly from Wuhan, China and its surrounding area. All subjects were screened by means of a detailed questionnaire, medical history taking, and physical examination. Menopause was defined as 1 year with no menstrual flow.

Subjects were excluded from the study if they had oligomenorrhea or a menorrhea before the age of 40 years or if they had such conditions affecting bone metabolism as diseases of the kidney, liver, parathyroid, or thyroid, diabetes mellitus, hyperprolactinemia, oophorectomy, rheumatoid arthritis, ankylosing spondylitis, malabsorption syndromes, malignant tumors, hematologic diseases, previous pathological fractures, hypertension, coronary artery disease, angiopathy, myocardial infarction, cerebral infarction, and infectious disease. If the subjects had received treatment with glucocorticoids, estrogens, thyroid hormone, parathyroid hormone, fluoride, bisphosphonate, calcitonin, thiazide diuretics, barbiturates, anti-seizure medication, vitamin D and calcium-containing drugs, they were also excluded. Body height and weight were measured using a stadiometer and a standardized balance-beam scale, respectively. This study was approved by the Research Ethics Committee of Wuhan Union Hospital, and informed consent was obtained from each woman before the study.

Among the postmenopausal women, 40 were considered osteoporosis according to the WHO criterion: Bone Mineral Density (BMD) more than 2.5 SD below the normal adult mean based on the established reference databases. 40 women whose BMD was less than 1.0 SD below the normal were included into the normal group. 40 volunteers were osteopenia whose BMD were between 2.5 SD and 1.0 SD.

Metabolic assays

Blood samples were collected between 7:00 a.m. and 8:30 a.m. after fasting overnight and allowed to clot. Thereafter the samples were centrifuged and divided into aliquots and stored at -70°C until being assayed. The serum concentration of OPN, MMP-3, OPG and OPGL was measured with ELISA kits (Boster Biosciences Co., Wuhan, China). The intra- and inter-assay CV were less than 5.6% and 6.2% for OPN, 6.5% and 6.0% for MMP-3, 5.4% and 6.9% for OPG, 6.5% and 6.7% for OPGL, respectively. Serum OPG levels were measured using ELISA kits (Boster Biosciences Co., Wuhan, China). Then the ratio of OPN to MMP-3 (list by OPN/MMP-3) and OPG to OPGL (list by OPG/OPGL) were calculated.

Measurements of BMD

BMD at the lumbar spine (L1–L4), the left hip including the femoral neck, trochanter and Ward's triangle was measured by Dual Energy X-Ray Absorptiometry (DEXA) using a Lunar-prodity device (GE, Mass, USA).

All BMD results were expressed as g/cm^2 . The precision of the DXA was evaluated over three repeated measurements of different BMD values in subjects, giving a mean coefficient of variation (CV) (range: 0.33%–0.40%) [4]. Phantom scan over the control spine was performed everyday with a long-term (more than 5 years) CV of 0.33%–0.40% and a root-mean-square coefficient of variation of 0.35% (degrees of freedom (df) = 1, 482).

Statistical analysis

Statistical analysis was made with the SPSS 13.0 software. The results were expressed as mean \pm Standard Deviation (SD). The correlations between OPN, MMP-3 and OPG, OPGL, BMD were assessed by Pearson's product-moment correlation coefficient and partial correlation analysis after adjustment for age and body mass index (BMI). Comparisons were made by one-way ANOVA. P value less than 0.05 was considered statistically significant.

Results

Characteristics

Among the 120 postmenopausal women, 40 age-matched normal controls, 40 age-matched osteopenia and 40 age-matched osteoporotic women were compared for the concentrations of Characteristics (Table 1) and serum OPN and MMP-3 (Table 2).

Among groups, there was no significant difference in age, BMI, and years after menopause ($P > 0.05$). Table 2 shows that the concentrations

of serum MMP-3, OPN and the ratio of OPN to MMP-3 were significantly higher in women with osteoporosis than in age-matched normal controls ($P < 0.01$). The concentrations of serum OPG were significantly higher in osteoporosis than normal controls ($P < 0.05$). The BMD at various skeletal sites and serum calcium concentration in women with osteoporosis were significantly lower than those in normal controls ($P < 0.05$).

Correlation of OPN, MMP-3 and OPN/MMP-3 with bone metabolism marker and BMD

Significant negative correlations of OPN and MMP-3 with BMD and OPGL were observed in all skeletal regions, and positive correlations of OPN and MMP-3 with OPG and OPG/OPGL were seen. After adjustment for age and body mass index (BMI), the above correlations were decreased but remained significant (Table 3).

In osteopenia, only significant correlations of MMP-3 with BMD of lumbar spine and ward angle were detected. In osteoporosis group, significant correlations of MMP-3 and ratio of OPN to MMP-3 with OPG, OPGL and BMD in all skeletal regions were detected (Table 4).

Discussion

OPG-OPGL system was associated with activating and differentiating of osteoclasts in osteoporosis. Over-expression of OPG in transgenic mice might lead to severe osteopetrosis associated with a decrease in osteoclasts in metaphyseal trabecular bone [5]. In contrast, OPG-deficient mice exhibited an overall decrease in total bone density and a high incidence of fractures, reminiscent of postmenopausal osteoporosis in human populations [6]. As the same time, the ratio of OPG to OPGL was more relative with estrogen than OPG and OPGL. In our study, levels of OPG, OPGL and the ratio of OPG to OPGL in osteoporosis were more than the normal, so that postmenopausal women of osteoporosis were in high turn-over bone metabolism statue. MMP could degrade extra-cellular matrix of bone, especially in postmenopausal osteoporosis. In low estrogen level, MMP would activate osteoclasts maturing, immigrating and sticking according to degrading the matrix [7].

MMP-3, also known as stromelysin-1, was secreted by osteoblasts, when estrogen was deficient, osteoblast was stimulated by osteoclasts, and therefore MMP-3 was much expressed in matrix around osteocyte and its lacuna in order to participate in collagen II and cartilage metabolism. In past, MMP-3 was considered to degrading non-collagen, such as proteoglycan not to act on collagen I metabolism [2, 8], but trigger bone resorption and formation. In recent [9], matrix metalloproteinases family was high linked to small integrin-binding

	Case	Age (yr)	Hight (cm)	Weight (kg)	BMI(kg/m ²)	Years after menopause (yr)
Normal	40	52.36 \pm 2.56	156 \pm 6	53 \pm 3	23.16 \pm 2.58	3.87 \pm 1.36
Osteopenia	40	52.98 \pm 3.64	155 \pm 4	56 \pm 4	22.26 \pm 3.04	3.84 \pm 1.59

Table 4: Relation of Serum Level of MMP3· OPN and Bone Biomarker in osteopenia and osteoporosis

ligand, N-linked glycoprotein family. The latter who combined with and activated the former take great part in the mineralization of bone.

Osteopontin (OPN) is a 34-kDa acidic, secreted phosphoprotein that was originally identified as a major component of the non-collagenous bone matrix expressed in both osteoblasts and osteoclasts. It has been found to be associated with bone strength and bone remodeling. Previous reports have indicated that OPN knockout mice are resistant to ovariectomy-induced bone resorption compared with wild-type mice. It have been proved that OPN were much more relatives to osteoporosis [3]. In our study [9], OPN in osteoporosis was much higher than in normal, so that postmenopausal women of osteoporosis were in high turn-over bone metabolism statue.

In pre-matured bone tissue, non-collagen was modified by OPN-MMP-3-complexity before bone matrix was mineralized in order to maintain local micro circumstance by protein-lyses of complexity. It was in osteoporotic metabolism triggered by osteoclasts that osteoblasts was crawling and surviving in mineralizing and high bone turn-over situation [10, 11]. In our case, levels of MMP-3 and OPN in osteoporosis were high than the normal and both were relatives with bone mineral density and OPG/OPGL. It was shown that MMP-3 was probably the triggered factor of postmenopausal osteoporosis and OPN-MMP-3 complexity was probably the bridge to explore the onset of PMOP.

Conclusion

Serum MMP-3 and OPN/MMP-3 would be the determinant factors of postmenopausal osteoporosis. They are correlated with markers of bone metabolism and their concentrations are increased in bone-turnover. They might be changed as a concomitant bone metabolic event in bone metabolism such as postmenopausal osteoporosis.
