

Farmer Participatory Evaluation of Agronomic performance of Malt Barley (*Hordeum vulgare L*) in the high land of Wollo, North eastern Ethiopia

Akalu Gebru* and Firew Mekbib

Department of Science, Sirinka Agricultural Research Center, Woldia, Ethiopia

Abstract

Malt barley (*Hordeum vulgare L.*) is one of the most important industrial crop and highly demanded due to the expansion of brewery factories in the country and the unique nature of the grain for malt. However, its production and productivity is very low compared to other countries due to limited numbers of high yielding malt barley varieties, partial use of agronomic and production and low genetic base due to these farmers were highly resistance to produce malt barley in north eastern Ethiopia. The objectives of this study were to identify malt barley varieties preferred by farmers. Seventeen varieties were evaluated in participatory variety selection (PVS) using RCB design, in Eastern Amhara. The varieties differed significantly for most of the characters and had wide range of mean values, which indicated the existence of variations among the tested varieties. Participatory variety selection was done using pair wise ranking and direct matrix ranking methods. It provides an opportunity to the farmers for variety selection and creates a chance to adopt the new selected varieties easily. Variety HB-1533, IBON174/03, EH-1847 and Friegbs scores the highest yield and highly preferred by farmers which perk up by the community. The above varieties were selected for further multiplication, seed dissemination.

Keywords: Direct matrix ranking • Genetics advance: Heritability • Pair wise rankig methods

Introduction

Barley (*Hordeum vulgare L.*) is an ancient domesticated crop belongs to the family Poaceae, it consists of 32 species with the diploid ($2n=2x=14$), tetraploid ($2n=4x=28$) and hexaploid ($2n=6x=42$) cytotypes in a basic chromosome number $x=7$, and self-fertility, large chromosome (6-8 μm) high degree of natural and easily inducible variation, ease of hybridization, ease for doubled haploid production and wide adaptation. Globally, barley ranks fourth among the cereal crops after wheat, maize and rice. It has superior nutritional quality due to the presence of beta-glucan (anti-cholesterol substance) and easily digestible due to low gluten content with high vitamin B group. Barley is a cool-season crop that adapted to high altitudes and grows in a wide range of agro climatic regions under several production systems.

Malt barley more preferred to food barley for especially in industrial purpose owing to its unique characters, relatively higher economic return to the farmer and good brewery products other than food crops. However, the big problem that faced barley production in the country was low production per unit area of land. The national average yield of malt barley production estimated at 1.5 ton/ha [1]. Which is very low compare to world average yield 2.9 ton/ha. Low productivity is attributed to the use of old and obsolete variety, low soil fertility, poor weed management, inappropriate fertilizer application. Moreover, in the country conventional research farmer don't involve both in problem identification and evaluation of research result. Consequently, most improved technology had suffered to low rate of adoption [2].

Participatory research increases the job efficiency of the scientists and research costs can be reduced and adoption rates increased if farmers are allowed to participate in variety testing and selection. In addition, production

increases when farmers adopt new varieties identified in participatory research [3,4]. Participatory variety selection (PVS) is an approach to provide a great chance to the farmer choice of variety for increasing production in their diversity, socio economical and agro ecological condition. Participatory variety selection approach has provided information to feed back in to the varietal development program and provide direct information technology transfer process by highlighting promising variety and adoption of new variety that address the needs of the farmers and more helps to faster introduction of the new variety to the community. PVS helps to identified preferred cultivars that consist of farmer needs which contain suitable materials to the farmers and fits to the farmers' field. Moreover, once identified variety there were great chance to adapt to climate change, and easily acceptable thereby overcome the constraints that cause farmers to grow old or obsolete varieties [5]. In farmer preferences, farmer gave an important attention to characters other than yield, and that were typically importance to small-scale farmers, such as seed color, spike length, plant height, tiller, seed size, seed per spike, frost resistance, drought resistance, color, overall performances, have been crucial for the increase adoption or rejection of new crop varieties. A farmer can weigh the various characters at least as good as the breeder, since she/he knows the best importance of each of the characters in relation to his or her farming system. Therefore, the main objective of these of experiment is identified preferred malt barley variety by farmer [6,7].

Methods

Description of the study area

The experiment was conducted in Amhara region, Geregra (north

Experimental design and field lay out

The trial was laid out in Randomized Complete Block Design (RCBD) with three replications. The plot size was 1.60 m wide and 2.5 m long with a total area of 4 m² consisting of 8 rows. The spacing between rows, plot and replication was 20 cm, 0.5 m and 1 m, respectively. The experiment was planted following the farmer trends. The seed rate was 100 kg/ha, and seeds were drilled in each row. Fertilizer was applied 41/46 of (N/P2O5) per hectare.

Farmers' preference evaluation

Twenty three representative and model farmers were participated in the malt barley variety selection. Participant farmers were selected based on their indigenous knowledge on barley production. Selected farmer makes focus group to assess all farmers view and perception on each variety which helps the farmers involving in planning, excursion, monitoring and promotion of new variety and targeted to enhance on farm varietal diversity. Varieties selections were conducted using focus group discussion (FGDs) using participatory tools such as Pair wise ranking and Direct Matrix ranking methods. The criteria included agronomic characters such as frost resistance, drought resistance, earliness (dates of heading, dates of maturity) spike length, seeds per spike, yield performance, and color. A few farmers had the chance to evaluate the varieties starting from emergency to maturity and some farmer visited the trials at the heading stages but the overall performances of the variety were evaluated and make selection at maturity stage.

The ranking procedures were explained to the farmers and they ranked each variety by observing the whole experimental units. Scores were given to each variety based on the selection criteria (1=very good, 2=good,

3=average, 4=poor and 5=very poor). Each farmer had a right to select from one to five to score and multiplied by the number of farmer to set cumulative rank and the cumulative rank also multiplied by the weight of the characters to standardized the rank of the final result selected variety the total scores a given variety. According to Boef and Thijssen (2006) scoring and ranking were done on consensus of participating farmers, where difference were solved by discussion in pair wise ranking but in direct matrix ranking each had a right to score 1-5. Both men and women were equally involved in the variety selection process. The degree of correlation coefficient in farmer preference and actual grain yield (After measuring actual yield) by using spearman correlation coefficient by using the following formula.

$$rs=1-(6\sum d^2)/(n(n^2-1))$$

Where, rs=correlation coefficient

d=difference in the ranks assigned to the same individual or phenomenon and

n=number of individuals or phenomena ranked

Results

Five malt barley varieties were selected as the best varieties for malt barley production which were HB-1533 and IBON 174/03 ranked first and second followed by Beka, miscal-21 and EH-1847. In other hand Varieties HB-120, HB-52, Holker, HB-1963 and Grace scored lowest rank. Farmer preference indicated that variety EH 1847, Frigebs and HB-1533, and IBON, 174/03 relatively short days to head and mature with good yields which have the capacity to give good yield (Table 3).

Frost resistance, drought resistance, earliness, yield performance, spike length, seed per spike and biomass were an important selection criterion for farmer relation to escape the frost and moisture stress in the study area and provide food security in the highland of the country and import substitution of malt barley in the country. Variety IBON 74/03 and HB 1533 scored short days to head and mature due to this more preferred

variety for production. Farmer point out which is frost and moisture deficit was the major barley production problem. Due to these farmers select the above variety for production. Almost all tested variety had similar grain filling period. The overall correlation coefficients in pair wise ranking methods with actual grain yields in farmer preferences acceptability ranks score 69%. Moreover, HB1533, and variety IBON 174/03 showed goods coincidence in

ranks of the yield and farmer preference (Table 4).

Discussion

According to analysis of variance and farmer evaluation five malt barley varieties were selected as the best varieties which were HB-1533 and IBON-174/03 ranked first and second followed by Beka, fanaka, misca-21 and EH-1847. Whereas, Varieties HB 120, HB 52, Holker, HB 1963 and grace scored lowest rank at the lowest. Farmer preference indicated that variety EH-1847, Frigebs and HB-1533, and IBON, 174/03 relatively short days to head and mature with good yields which have the capacity to give goods yield for home consumption. Farmers were more impressive especially on Variety IBON 174/03 in early heading and mature with average yield performance.

Most farmers revealed that the reasons for the preference of a variety were related to many characters which help to solve the problem that hinder their maximum production. Frost resistance, drought resistance and earliness remains as an important selection criterion for farmers related to escape the frost and moisture stress in the study area and provide foods in the highland of the country. Developing variety which is frost and drought resistance is the priority agenda for farmers in their selection criteria. So far the areas were highly affected by frost and terminal moisture stress. Farmers strongly focused on yield performance in related to tiller and earliness to escape the above production problem and to get reasonable yield. When a variety is resistant to frost or early maturity before frost and drought appear, is the ultimate goal of the farmer. Large seeds size were more attractive and produce large grain with more powders thereby increase yield. The next important character was seeds per spike, when the numbers of seed per spike high grain yield per plot. Plant height was not that much important for selections criteria followed by color. But if the above criterion fulfills long plant height, long spike length along many seeds per spike with white color preferred by the farmers.

Participatory variety selection is a more rapid and cost effective way of identifying variety to produce farmer acceptable variety, particularly the areas with terminal moisture stress. The selected varieties were suggested for these niches after validation of results through farmer preference and

analysis of variance to confirm the real performance which helps is used for up scaling. Identified variety for predication potential need to be popularized through in the highlands area of wollo and surrounding barley production belt area to cover large potential area for supplying malt barley grain for malt factory.

Conclusion

Spearman rank correlation is non-parametric test that is used to measure the degree of association between two variables and see the degree of coincidence between farmers' acceptability rank and actual yield rank, (Grain Yield after measuring actual yield). Varieties HB1533, and IBON 174/03 had showed that 100% coincidence the actual yield and in the field condition in farmer preference. However, the overall correlation coefficients in pair wise ranking and direct matrix ranking methods with actual grain yields in farmer preferences acceptability ranks score 69% and 65% respectively.

Conflict of Interest

We have no conflict of interests to disclose and the manuscript has been read and approved by all named authors.
