Abstract

Different beer brands produced in Ethiopia were surveyed for the presence of Cd, Cu, Pb, Mn and Zn. The samples were digested in nitric acid and hydrogen peroxide, and analysed by atomic absorption spectrometry equipped with deuterium arc background corrector. The mean concentrations of metals in beer were as follows: Cd, 0.0014 mg/l; Cu, 0.0368 mg/l; Mn, 0.0954 mg/l; Pb, 0.0066 mg/l; Zn, 1.5206 mg/l. The estimated daily intakes were calculated based on Ethiopian annual per capita beer consumption of 8.75 liters. The mean intakes of Cd, Cu, Pb, Mn and Zn through beer were estimated to be 0.0006, 0.0232, 0.0024, 0.0378 and 0.6076 μg/kg bw/day, respectively. The risk assessment of mean levels indicated that health risk associated with these heavy metals through consumption of beer was absent.

Keywords: Beer; Estimated daily intake; Heavy metal

Introduction

Heavy metals are introduced into the environment by both natural and anthropogenic causes. Human activities like metal mining, smelters, shredder plants and waste depositing and incineration have increased the concentration of metals within the natural environment thereby increasing their mobilization to a level exceeding that of their natural concentration. Expansion of industries greatly increased the levels of toxic elements in the environment. Moreover, increased use of chemical fertilizers and pesticides can also lead to an increase in heavy metal concentrations in soil and plants. Accumulation of such metals in soil and plants becomes a serious issue because of the potential human health risks [1-3].

Some heavy metals have nutritional functions and are essential to maintain the metabolism of the human body. Metals like Cu, Mn and Zn are essential for physiological processes; certain enzymes need metal ions for their catalytic activity. On the other hand, Cd and Pb are toxic metals. All of them may be harmful if excessive amounts are consumed [2-5]. Cadmium is a highly toxic element that accumulates in biologic systems and has a long half-life. Generally, the Cd content in alcoholic beverages has been found to be quite low; however, when the consumption of large amounts of certain beverages causes the dietary intake of Cd to reach the maximum allowable levels, it may be physiologically significant [6]. Lead is also a toxic heavy metal widely distributed in the environment. The entry of lead into the food chain is a major concern, because of its toxicity. Lead has strong effects on haem biosynthesis and erythropoiesis [7,8]. Even though Cu is one of the essential elements, its intake at high concentration is associated with oxidative stress, diminished activities of antioxidant enzymes and subsequent tissue damage [9]. Similarly high level of Mn causes toxicity to humans, often called Mn induced parkinsonism [10] while excess amount of Zn can cause system dysfunctions that result in impairment of growth and reproduction [11].

Humans are exposed to essential and toxic heavy metals from various sources, including the contaminated atmosphere, food, water or soil. Consuming food crops contaminated with metals is a major food chain route for human exposure. This food chain contamination is one of the important pathways for the entry of these toxic pollutants into the human body. For example, food contamination is the most important pathway of Cd exposure to the general population. People receive the largest portion of their daily Pb intake through food. Lead can enter food during storage and manufacture, e.g. in canned foods and in alcoholic drinks [7,12].

Metals can be transferred from the soil to plants from which an alcoholic beverage is prepared [13]. Beer is one of the most consumed alcoholic beverages in Ethiopia, yet no data exist on the metal contents of beer produced in Ethiopia. In order to bridge this gap, this study was undertaken to determine the concentrations of Cd, Cu, Pb, Mn and Zn in locally produced beer brands, with a view to provide information on the average daily intake of these metals from consumption of these products.

Materials and Methods

Sample collection

The samples of locally produced beer brands were collected from ten randomly selected grocery stores in Addis Ababa, the capital city of Ethiopia in February 2011. There are five beer brands (Bedelle, Dashen, St. George, Harar and Meta) that produced in Ethiopia. Beer samples were collected as described by the European Commission [14]. The percentage of alcohol by volume in the samples ranged from 4.5 to 5.5%. The samples were stored at 4°C until analysis was completed.

Sample preparation

Prior to analysis, all beer samples were degassed using an ultrasonic bath for 30 min [5]. Samples were digested according to the methods described in [15]. Exactly 20 ml of the degassed beer portions were...
digested on a hot plate prior to the determination of heavy metal concentrations. Accordingly, samples were placed into 100-ml glass beakers and covered with watch glasses in order to prevent contamination. To evaporate alcohol and reduce the sample volume to about 1 ml, they were allowed to boil at about 100°C. Care was taken to avoid spattering. Then, 3 ml of concentrated nitric acid (65% HNO₃) was added and the samples were evaporated nearly to dryness. After cooling, 5 ml of hydrogen peroxide (30% H₂O₂) was added to the residues and heating was continued until the volume was again reduced to about 1 ml. The aliquots left were mixed with little water and diluted to 10 ml for analysis. Analytical blanks were prepared in a similar manner, but omitting the test sample. The solutions were subsequently analyzed for metals using flame atomic absorption spectrometry equipped with deuterium arc background corrector (PG990, United Kingdom).

Quality control

Appropriate quality assurance procedures and precautions were carried out to ensure the reliability of the results. Samples were handled carefully to avoid contamination. All glassware and other containers were properly cleaned and the reagents were of analytical grade. Distilled deionized water was used throughout the study. Reagent blank determinations were used to correct the instrument readings. Accuracy of the digestion procedures was verified by examination of the recovery data, spiking analyzed samples with aliquots of metal standards and then reanalyzing the samples. The percentage recoveries lay within the range 87.6-104.68% with the percent relative standard deviations less than eleven, indicating good accuracy and precision. Limits of Detection (LOD) were calculated as three times the pooled standard deviation of six runs of blank measurements. LODs of Cd, Cu, Mn, Pb and Zn were 0.006, 0.011, 0.009, 0.020 and 0.042 mg/kg respectively.

Statistical analysis

The analysis of variance (ANOVA) and Tukey post hoc test were performed to find differences between the means of samples at 95% confidence level and to know specifically which groups differed significantly from the other groups. Data were analyzed statistically using SPSS® statistical package version 13.0.

Results and Discussion

Metal content of beer samples

The mean concentrations (± standard deviations) of metals considered in the different brands of beer and their maximum tolerance limits set by the Brazilian legislation in alcoholic beverages [16] are presented in (Table 1). Bedelle beer contained the highest concentration of manganese (0.202 mg/Kg) among beer brands. Both Cd and Pb were not detected in Bedelle beer. Copper (0.016 mg/Kg) was found at much lower concentration than Mn and Zn in this brand. Bedelle beer can contribute to higher Zn intake than Cu and Mn intakes. The mean concentration of Cu (0.052 mg/Kg) was also lower than Mn (0.091 mg/Kg) and Zn (1.697 mg/Kg) in Dashen beer while Cd and Pb were not detected in this beer brand. Dashen beer also contributes towards higher Zn intake than Cu and Mn intakes. The only beer brand observed to contain Pb was St. George (0.03 mg/kg). Zinc (1 mg/Kg) was present at higher concentration in St. George beer than Mn (0.091 mg/Kg) followed by Cu (0.048 mg/Kg). However, Cd was not detected in St. George beer. St. George beer was the only beer that contributed Pb to the total dietary intake. In Harar beer, the level of Zn (0.599 mg/Kg) was higher than Mn (0.051 mg/Kg) and Cu (0.056 mg/Kg). On the other hand, Cd and Pb were not detected in Harar beer. Harar beer brand, like Bedelle and Dashen beers, contributed to higher Zn intake than Cu and Mn intakes. Meta beer was the only beer observed to contain Cd (0.007 mg/Kg). It also contained the highest concentration of Zn (3.528 mg/Kg). In contrast, Cu (0.012 mg/Kg) and Mn (0.042 mg/Kg) were present in Meta beer at the lowest concentrations than the other brands of beer. Meta beer was the only beer that contributed Cd to the total dietary intake.

The concentrations of Cd, Cu, Pb and Zn in the different brands of beer were below the regulatory limits for alcoholic beverages set by the Brazilian legislation. The concentration of heavy metals in beer is also recommended not to exceed the maximum permissible limits in drinking water since beer contains more than 90 percent of water [16]. However, limits imposed for alcoholic beverages are higher than those established for water utilized for human consumption due to lower intake of the former [13]. Since limit for Mn in alcoholic beverages has not been set by the Brazilian legislation, its levels were compared with permissible limits in drinking water. Manganese contents of the beer samples were below the WHO maximum permissible limits in drinking water, 0.4 mg/l [17].

The level of metals in beers is highly affected by the soil type on which the cereal grains are cultivated, the use of fertilizers, pesticides and fungicides, and the surrounding environmental pollution [13]. Chen et al. [18] reported that there are differences among the barley varieties in their ability to accumulate heavy metals in grains. Moreover, brewing water is the source of heavy metals such as Cd and Pb found in beer [19]. During the brewing process, the metal content of beer could be also affected by the components of the brewery equipment like pipes, fluid lines, vessels and tanks, and other materials involved in the process [20]. Cadmium in beer and other alcoholic beverages could be due to raw material contamination and technological processes [6]. Zinc may originate in the raw materials, brewing liquor or substances added during brewing. Small amounts of zinc may be also picked up from the brewing plant [21].

Comparison of the metal levels in beer samples with reported data

A comparison of the results obtained in this study with values found in literature is presented in (Table 2). The concentration of Cd in the present study is comparable to the levels reported in beers available in Nigeria [22], Italy [5] and Brazil [23]. The levels of Cu obtained in this work are in agreement with that of other studies in Nigeria [22], Brazil [24] and Norway [25]. The lead level observed in this study is in line with that of other surveys [5,22,24]. For Mn the results obtained in this work are comparable to the levels reported in beers from Poland.
Human exposure to heavy metals through beer

The estimated daily intake of metals was calculated based on the amount of beer daily consumed and heavy metal levels of the beer samples. Ethiopian annual per capita consumption of beer was 8.75 liters per person aged 18 and over (Ethiopian legal drinking age) in 2008 with estimated country wide consumption of 3.1 million hectoliters [27,28]. The estimated daily intakes through beer are shown in (Table 3).

All the estimated daily intakes of the target metals calculated based on annual per capita beer consumption were below the tolerable daily intake set by the World Health Organization and hence they could not cause any negative health impact on the consumers. The health risk index (HI) described by the percentage of the safe value was used for the risk assessment. As shown in Table 3, the data of HI were all less than 1 for the mean exposure, which indicated that there was no potential health risk to general people.

Conclusion

This survey showed that the mean levels of Cd, Cu, Pb, Mn and Zn in different locally produced beer brands were below the maximum tolerable limits in alcoholic beverages established by the Brazilian legislation. The mean daily exposures were estimated based on annual per capita beer consumption to be safe. Therefore, contribution of the investigated brands of beer to the dietary exposure of heavy metals does not pose a health risk to consumers with regard to these elements.
