Abstract

We propose to contribute to the emerging body of cancer treatment research by developing and analyzing mathematical models of the treatment of tumor with various strategic treatments. We build on existing models of the immunology that are already successfully developed and then the effects of chemotherapy and interleukin-2 were applied to the model. Thus we build a mathematical model of tumour and effector cell with scheduled chemotherapy.

The effect of scheduled i2 dose with chemotherapy and adoptive immunotherapy reduced the tumor growth.

Keywords: Mathematical modeling; Chemotherapy; Effector cell; IL-2; Adoptive immunotherapy

Introduction

The worldwide burden of cancer (malignant tumor) is a major health problem, with more than 8 million new cases and 5 million deaths per year. Cancer is the second leading cause of death. With growing techniques the survival rate has increased and so it becomes important to contribute even the smallest help in this field favoring the survival rate. Tumor is a mass of tissue formed as the result of abnormal, excessive, uncoordinated, autonomous and purposeless proliferation of cells.

The immune system plays an important role to identify and eliminate tumors. This is called immune surveillance. The theory of immune surveillance says that the immune system continually recognizes the transformed cells of tumors because they express antigens that are not found on normal cells. For the immune system, these antigens appear foreign, and their presence causes immune cells to attack the transformed tumor cells and hence eliminates tumor cells, but when a tumor escapes immune surveillance and grows too large for the immune system to kill, tumor is the result. Tumor antigens are presented on MHC (Major Histocompatibility Complex) class I molecules (present on the surface of tumor cells) in a similar way to viral antigens. This allows killer T cells to recognize the tumor cell as abnormal. NK (Natural Killer) cells also kill tumorous cells in a similar way. Tumor-specific lymphocytes are lymphocytes of immune system which recognizes tumor cells and can be found in the blood, draining lymph nodes, and the tumor itself of patients with actively growing tumors.

The main response of the immune system to tumors is to destroy the abnormal cells using killer T cells, which generally require several stimuli for rapid expansion. It has been known for long time that interleukin-2 (IL-2) is generally required for expansion of populations of T lymphocytes in vitro [1]. IL-2 is a cytokine which is used in treating advanced cancer taken alone or with combinations with other drugs.

IL-2 causes effector cells to proliferate. However IL-2 can also activate natural killer cells, B lymphocytes, and macrophages and can induce lymphokine-activated killer cells in vitro. High dose intravenous bolus of IL-2 is administered to treat many types of melanomas. But the problem with high dose of IL-2 therapy is that it causes toxicity and many types of side effects to the body and even can cause death [2].

At present, chemotherapy is the most well established treatment for fighting cancer. Chemotherapy, in its most general sense, is the treatment of disease by chemicals especially by killing micro-organisms or cancerous cells. The basic idea behind chemotherapy is to kill cancerous cells faster than healthy cells. This is accomplished by interrupting cellular division at some phase and thus killing more tumor cells than their slower developing normal cells. The course of therapy depends on the cancer type, the chemotherapy drugs used, the treatment goal and how your body responds. The treatment may be given every day, every week or every month. Their may be breaks between treatments so that the body has a chance to build new healthy cells [3,4]. However some normal cells, for example those that form the stomach lining and immune cells, are also rapidly dividing cells which means that chemotherapy also harms the patient leading to things like a depressed immune system which opens the host to infection [5,6]. In addition, chemotherapy causes significant side effects in patients, and therefore exploring new forms treatments may prove extremely beneficial.

One of the form of immunotherapy to treat the tumor growth is Adoptive immunotherapy. It is used in treatment of tumor in which lymphocytes are removed from the patient’s body to enhance their anti-tumor activity with naturally produced growth factor, cultured in large numbers and then returned to the patient. Adoptive immunotherapy uses immune effector cells as lymphocytes. Lymphokine-activated killer (LAK) cells and Tumor-infiltrating lymphocytes (TILs) are such lymphocytes which are grown in presence of IL-2 an immune stimulator [7].

Despite the existence of anti-tumor immune responses, the tumors still progress and eventually cause disastrous effects on host body. Over the past several decades, investigators have pursued variety of strategies to direct the immune system against many types of tumors. The immune responses to be effective enough must eliminate the tumor cells more rapidly than their rate of proliferation and hence the role of boosting the immune response or immunotherapy. In this article we present a model of immune system against tumor growth. Chemotherapy and...
immunotherapy are not that success in treatment even high doses of these therapies are effective for tumor eradication but also high doses of these treatments create severe side effects in the body [8].

The growing understanding of the therapy cycles has produced various strategies to increase the effectiveness of cancer treatment [9]. Hence, In this paper a model of tumor growth is presented which describes the treatment of a tumor by chemotherapy over a fixed period of time by the repeated administration of its doses. The model will select that in what interval, at what schedule and what specific doses of IL-2 therapy, chemotherapy and adoptive immunotherapy should be delivered. The model constructs a regimen that both minimizes the tumor population at the end of the treatment and satisfies constraints on the drug toxicity and intermediate tumor size.

Mathematical Modeling

The model consists of four ordinary differential equations of immune response to tumor growth which gets affected by treatments chemotherapy, interleukin-2 and adoptive immunotherapy. The following variables are set to the model (Table 1).

**Effector cell**

Effector cells are lymphocytes which are the relatively short-lived activated cells that have been induced to differentiate into a form capable of mounting a specific immune response. The production of the effector cell was given by Kirschner [10] and shown below that how chemotherapy affects the production of the effector cell.

\[ \frac{dx}{dt} = cy - \mu_x x + p_1 \frac{xz}{g_1 + z} - C_x (1 - e^{-\tau t}) x + S_1 \]

(1)

In this equation, \( c \) denotes the antigenicity of tumour. Tumor antigen are main target for cancer immunotherapy. The ideal tumor antigen is immunogenic and expressed exclusively on tumor cells. Higher the value of antigenicity the easier it becomes for the effector cell to detect the tumor. The second term is the mortality rate of effector cell and the third term is the proliferation term due to the presence of the cytokine IL-2. Here \( p_1 \) is the maximum proliferation of the effector cell. The fourth term denotes the chemotherapeutic effect on effector cells. The interaction of chemotherapy on sensitive cells is given by saturation term kinetics [11]. At low chemotherapeutic drug doses the death rate of the cells depends on the chemotherapeutic drug \( x(t) \) but at high doses it becomes \( \lambda \) independent. It is assumed that \( C_x \) depends on the IL-2 concentration [12]. The fifth term \( S_1 \) denotes a treatment called adoptive immunotherapy at constant influx.

Here, \( C_x = c_{chemo}(1 - e^{-z_{chemo} t}) \) where \( C_x^{chemo} \) is the death rate of effector cells by chemotherapy, and \( z_{chemo} \) is IL-2 \( x(t) \) at \( t=0 \).

**Tumor cell**

The interaction of immune system with tumor is again based on the Kirschner model.

\[ \frac{dy}{dt} = r_y (1 - by) - \frac{axy}{g_2 + y} - C_y (1 - e^{-\lambda t}) y \]

(2)

In this equation the first term denotes the production rate of the tumor cells having maximum proliferation rate of \( r_y \) until it reaches to its carrying capacity \( b \) of tumor [13]. The second term shows that the destruction by the effector cell \( x(t) \) and \( a \) is the parameter used to give value of the strength of the immune system against tumor cells [14]. The third term denotes the effect of the chemotherapeutic drug on tumor cells.

Here, \( C_y = c_{chemo}^{chemo}(1 - e^{-z_{chemo}}) \), where \( C_y^{chemo} \) is the death rate of tumor cells by chemotherapy.

**IL-2**

The Kirschner model explains the production of the IL-2.

\[ \frac{dz}{dt} = p_3 xy - \mu_z z + S_2 \]

(3)

Here the first term is the production of IL-2 which depends on the interaction of the \( x(t) \) and \( y(t) \) and \( p_3 \) is the maximum proliferation of the IL-2. The second term is the decay rate of IL-2. \( S_2 \) denotes interleukin therapy at constant influx.

**Chemotherapeutic drug**

\[ \frac{d\lambda}{dt} = V(t) - v \lambda \]

(4)

Here, \( V(t) \) is the time dependent external influx of the chemotherapeutic drug and \( v \) is the decay rate.

Finally, writing all the equations representing the growth of tumor cells, immune system and chemotherapeutic drug and effects of treatments on tumour growth.

\[ \frac{dx}{dt} = cy - \mu_x x + p_1 \frac{xz}{g_1 + z} - C_x (1 - e^{-\tau t}) x + S_1 \]

\[ \frac{dy}{dt} = r_y (1 - by) - \frac{axy}{g_2 + y} - C_y (1 - e^{-\lambda t}) y \]

\[ \frac{dz}{dt} = p_3 xy - \mu_z z + S_2 \]

\[ \frac{d\lambda}{dt} = V(t) - v \lambda \]

**Parameter**

The tumor immune dynamics is sensitive to the choice of parameter values [15]. The parameter values changes from patient to patient. The experimental proved values are given below. But some values are studied from the medical history and which are not experimentally proved are fitted to the available data and studied their affects by giving different values on the model. The value of \( r_y \) is estimated to be \( 10^6 \) cells as after this value the angiogenic is switched on [16]. The parameter \( q_1 \) and \( q_2 \) were estimated by experiments presented in [14]. The values of \( C_x^{chemo} \) and \( C_y^{chemo} \) representing the killing of cells by chemotherapy are estimated from Pilli’s model [17]. The decay rate of the chemotherapeutic drug was estimated from the example taken from Kuznetsov VA, Makalikin IA [18] (Table 2).

Initially, \( x(0)= 1, y(0)= 1, z(0)= 1, \lambda(0)=0 \)

**Results and Discussion**

In this section, we present the numerical results to explore the effects of therapies on growth rate of tumor cells. For this purpose we used Equations 1-4 for tumor cell density, effector cell density, IL2 level
and chemotherapeutic drug respectively and applied different doses of treatment at different time intervals so as to study their effects on tumor growth. Computer program is developed in software MatLab and run on Pentium IV using ode15s.

Figure 1a shows the growth of tumor cells, effector cells and I2 growth without giving external therapies like I2 dose, chemotherapy and adoptive immunotherapy.

Table 2: The decay rate of the chemotherapeutic drug was estimated from the example taken from Kuznetsov VA, Makalkin IA [18].

Effect of chemotherapy

There are a number of strategies in the administration of chemotherapeutic drugs used today. Chemotherapy may be given with a curative intent or it may aim to prolong life or to palliate symptoms [19]. As we know that effector cell density is dependent on I2 level, if I2 level falls, effector cell density also drops. So, we kept chemotherapy schedule not only time dependent but also I2 dependent. Once the chemotherapy starts at some fixed time interval (time dependent) then the therapy is scheduled by I2 level (I2 dependent). This means that chemotherapy schedule is managed such as to keep effector cell density under control. A Mat Lab code is given such that chemotherapy starts (V=1) when x>required I2 level and chemotherapy stops (V=0) when x<the required I2 level. By keeping such we can know that at what time the chemotherapy should be started and in what intervals it should be given so as not to effect I2 level and effector cells too. Schedules and effects of chemotherapy doses are shown in following figures. The chemotherapy schedule, tumour density, effector cell density and I2 level are well observed from the simulations and then explained.

Figure 2 shows that proper and scheduled application of chemotherapy to the patient can be very effective. In Figure 2a the dose of I2 scheduled without chemotherapy does nothing whereas in Figure 2b the same dose of I2 scheduled with chemotherapy brings a big change. As the frequent chemotherapy doses are effective in treatment of tumors, (discussed in American Cancer Society [20]) So, here...
Chemotherapy is started from 108th day and is given after each 21 hours intervals such that il2  = 10000, on the other hand tumour cell density comes below to its carrying capacity to about 3995000 cells. This keeps the effector cells density also stable. The il2 dose of S2=200000 (which is less than the standard dose of 600,000 unit and high dose of 720,000 unit [21,22] is given from 1000th day for (a) 120 days and (b) 90 days. We see a sudden fall of tumor growth and finally at 1080th day the tumor gets eliminated. As soon il2 therapy stops the tumour vigorously grows. But this is lot time for other treatment including dietary regulations to stop further tumour growth.

Eradiation of tumour cells with effector cells. In Figure 3b il2 dose therapy is companied with adoptive immunotherapy of S1=500. We see recovery of effector cell growth after a down fall. This is one of the good ways to eliminate tumor cell keeping effector cells alive.

Figure 4 Here all the parameters are kept same as in Figure 2 except reduced dose of il2 of S2=100000. This shows long term eradication is possibe with application of long term adoptive therapy. But this is quite unrealistic.

**Conclusion and Future Work**

In this study various treatments with scheduled time and dose were discussed. It is clear from above discussion that for reducing tumour growth chemotherapy should be started as soon as the tumour is detected and chemotherapy should be scheduled frequently within few hours along with low doses of il2 so that the effector cells and also the host body gets frequent recovery time, which as a result does not harm the body by after effects of chemotherapy and il2 therapy. Also when the effector cell density drops to its half then the therapies should be companied with short term adoptive immunotherapy which may
eliminate the tumour. Different types of chemotherapy drugs kill cells at different stages of the cell cycle. Administering the specific drugs when the cancer cells are most sensitive and other cells are less sensitive makes them more effective. Some types of chemotherapy need to be activated in the body before they affect cancer cells; administering them at times when this will happen efficiently also improves effect. The clinicians and nutritionist, has the work to find out various ways to avoid tumor, once eradicated for further evolution.
