

The Market for Bioactive Materials: Developments and Prospects

Pornkul Suksod*

Department of Economics, Science and Technology, University of New York, New York, USA

Introduction

Antibacterial medication has long been used to treat infections. An antibacterial bioactive material is defined as a substance that has the power to destroy germs or inhibit their growth or reproduction. Infectious illness management has become a growing challenge for physicians in recent years. The rise of drug-resistant bacteria has made bacterial infection management harder. Hospital-acquired infections and the healthcare environment have received significant worldwide attention in recent years as a result of numerous incidences and outbreaks of and that caused morbidity and mortality. As worldwide players in the subject of health Economics. In the realm of health economy, a platform for life sciences has already been established, allowing for more collaborative ventures between both research and economy from both countries. As a result, several various research initiatives have already been carried out between the two countries. However, collaboration between researchers, physicians, and industry from various professions and fields is critical for development in biomaterial research and related products. Chemists, material scientists, biologists, and medics, among many others, are involved in this research field and hope to find mutual answers for tissue regeneration. As collaborative research and biomedical product markets become increasingly global, measures to preserve established cooperative research are important. Even these discussions resulted in the under the auspices of the and Research .The workshop was organised to allow people from the aforementioned and various research centres to exchange novel biomaterial-based application ideas and knowledge about the differing approval requirements of medical devices in both nations [1].

Furthermore, as a result of this event, the ministries of both countries have agreed to launch a special funding initiative called which will allow cooperation research between two consortia from both countries, each consisting of one university and one enterprise. From each different country this programme is a fantastic opportunity. Enabling various research institutions and firms to create new biomaterials or medical devices and learn more about the regulatory criteria in both countries In addition, this funding programme intends to maintain the existing collaboration between China and Germany in biomedical research and facilitate reciprocal access to respective biomedical markets. *Staphylococcus aureus*, *Staphylococcus epidermidis*, *Enterococcus faecium*, *Enterococcus faecalis* and *Streptococcus pneumoniae* are among the Gram-positive species. According to reports from many centralised agencies that track bacterial resistance trends, the prevalence of methicillin-resistant *aureus* has climbed from and vancomycin-resistant has increased from in the last three years. In hospitalised patients with hospital-acquired infections, these resistant pathogens are a major cause of morbidity and mortality .The problem of resistant Gram-positive germs, on the other hand, is not limited to the hospitalised patient. With the advent of penicillin-resistant a cause of

community-acquired pneumonia, outpatients have also been affected. The present worldwide anti-infective market is expected to be worth, with bioactive antibacterial agents accounting for more than half of sales. The antibacterial market is expected to exceed owing to the increased use of novel antibacterial agents such as glycol peptides and carba penems, which show resistance to and other developing pathogens. To address the major issue of antibiotic resistance, pharmaceutical companies are developing a new generation of antibacterial medicines such as cephalo sporins, macrolides, and quinolones. Furthermore, a number of new medication families, such as dihydrofolate reductase inhibitors are being tested in multi-drug-resistant species [2].

Description

The focus of this chapter is on bioactive materials with antibacterial functionality for use in the medical device and health care industries, such as wound care dental and orthopaedics and cardiovascular. This chapter discusses antibacterial inorganic polymers such as bioglass, ceramics, glass-ceramics, and zeolites; antibacterial composites such as bone cement; antibacterial metal; and antibacterial polymers and plastics. Heavy metals, such as silver, zinc, copper, mercury, tin, lead, bismuth, cadmium, chromium, and thallium, have antibacterial capabilities, and their exchange with inorganic polymers, such as zeolites and zirconium, confers antibacterial activity. The antibacterial effects of silver-supported zirconium phosphate or silica gel are attributed to the catalytic action of silver rather than the release of silver ion Antibacterial elements are commonly included into curable resins to create antibacterial composites for medical applications. Antibiotic-loaded polymethyl methacrylate bone cement, for example, has been proposed to lower infection rates [3].

The present worldwide anti-infective market is expected to be billion, with bioactive antibacterial agents accounting for more than half of sales. The antibacterial market is expected to exceed billion by owing to the increased use of novel antibacterial agents such as glycopeptides and carbapenems, which show resistance to and other developing pathogens. To address the major issue of antibiotic resistance, pharmaceutical companies are developing a new generation of antibacterial medicines such as cephalosporins, macrolides, and quinolones. Furthermore, a number of new medication families, such as dihydrofolate reductase inhibitors are being tested in multi-drug-resistant species. Antibacterial elements are commonly included into curable resins to create antibacterial composites for medical applications. Antibiotic-loaded polymethylmethacrylate bone cement, for example, has been proposed to lower infection rates [5].

Conclusion

Future research will be needed to better understand the pathophysiology of device-related infections and their effects on human homeostasis functions, such as the microstructure and chemical structure of the adherence mechanism, receptor sites in compromised tissue, and factors that may effectively block the initial bacterial adherence.
