Abstract

Bradycardia is commonly encountered in emergency department. Hyperkalemia may sometime cause bradycardia with block and also synergize with AV node blockers to cause bradycardia and hypoperfusion. We report a 53 years old male with history of hypertension, congestive heart failure and coronary artery disease was admitted to hospital for sudden onset of breathlessness. He underwent Percutaneous Coronary Intervention (PCI) to Left Anterior Descending (LAD) artery and Left Circumflex (LCx) artery one year ago and taking Aspilet 80 mg for daily, Clopidogrel 75 mg daily, Ramipril 5 mg daily, Atorvastatin 20 mg daily, Metoprolol 25 mg daily, Spironolactone 25 mg daily and Frusemide 40 mg daily. Significant physical examination was remarkable for a temperature 97.5°F, blood pressure of 110/70 mmHg, heart rate of 40 beats per minute, oxygen saturation was 99% on air and both lung were full with audible crepitation by auscultation. He was given atropine 0.6 mg bolus and transcutaneous pacing with unimproved heart rate and then a transvenous pacing was immediately placed before the blood investigation results were returned. His relevant laboratory values were significant for a potassium of 7.99 mmol/L (ref range: 3.5-5.2 mmol/L), creatinine of 458 micromol/L (ref range: 59-104 micromol/L), Urea of 33.9 mmol/L (ref range: 2.7-8.0 mmol/L), random blood glucose of 233 mg/dl, sodium 126.8 mmol/L (ref range 135-145 mmol/L), anion gap of 13.5 mmol/L (ref range: 3.6-11.0 mmol/L) and bicarbonate of 15.6 mmol/L (ref range: 22-29 mmol/L). He was given calcium gluconate, insulin with dextrose, kaexylate, nebulizer salbutamol with significant improvement in his potassium levels to 4.6 in 24 hours. In Cardiac intensive care unit his heart rate was improved and the transvenous pacemaker was turned off the next day. 

Keywords: Hyperkalemia • Bradycardia • Pacemaker • Heart block

Introduction

Bradycardia is commonly encountered in emergency department. Hyperkalemia may cause bradycardia with block and may also synergize with AV node blockers to cause bradycardia and hypoperfusion [1]. Potassium is vital for regulating the normal electrical activity of the heart. Increased extracellular potassium reduces myocardial excitability, with depression of both pacemaking and conducting tissues [2]. Progressively worsening hyperkalemia leads to suppression of impulse generation by the SA node and reduced conduction by the AV node and His-Purkinje system, resulting in bradycardia and conduction blocks and ultimately cardiac arrest [3].

Case Presentation

A 53-year-old man known to have coronary heart disease, congestive heart failure, type 2 diabetes mellitus and hypertension was taking Aspilet 80 mg for daily, Clopidogrel 75 mg daily, Ramipril 5 mg daily, Atorvastatin 20 mg daily, Metoprolol 25 mg daily, Spironolactone 25 mg daily and Frusemide 40 mg daily. His Underwent Percutaneous Coronary Intervention (PCI) to Left Anterior Descending (LAD) artery and Left Circumflex (LCx) artery one year ago. He presented to the emergency department in acute shortness of breath. Despite given IV Atropine, the heart rate remained extreme bradycardia with ventricular rate of around 40 bpm. So transcutaneous pacing pad was placed on chest shown in Figures 2 and 3 and sent to cardiac intensive care unit. In the cardiac care unit, immediate transvenous pacing (VVI mode) was implanted into right ventricle as his heart rate was still unimproved on transcutaneous pacing. Blood samples were sent for immediate determination of Arterial Blood Gas (ABG) concentrations, complete blood count, urea and electrolytes, liver function, and cardiac enzymes. His glucose level, determined by a finger stick, was 233 mg/dl. The patient was given IV atropine 0.6 mg bolus, started on intravenous frusemide 80 mg and nebulizer salbutamol 5 mg, and placed on a cardiac monitor. An immediate ECG was obtained Figure 1; showing marked bradycardia with ventricular response at rate of 45 bpm with variable block was noted in lead II and III.

If patients are found to be with bradycardiac, clinicians and medics should not miss life threatening hyperkalemic bradyarrhythmia due to electrolytes imbalance that may cause profound bradycardia or with different forms of heart block. The clue to the correct diagnosis is the broad QRS complex with absence of P waves. Hyperkalaemic related second and third degree Atrioventricular (AV) block may be seen sometime but they are uncommon because the P wave usually disappears before such advanced AV block occurs. If the ECG is available before the serum potassium and is consistent with life threatening hyperkalemia, then it would seem sensible to give calcium glucuronate speculatively while waiting for the biochemistry results. However, the prevalence of severe hyperkalemia accompanying symptomatic bradycardia has only been explored in a few case reports. Some authors have reported “BRASH” syndrome that can be seen due to a vicious cycle in the setting of medications, hyperkalemia, and renal failure [7,8].

Renal failure causes hyperkalemia which may cause the accumulation of some AV node blockers (e.g. Atenolol, Nadolol). Hyperkalemia synergizes with AV node blockers to cause bradycardia and hypoperfusion. Hypoperfusion, in turn, causes worsening of the renal failure [7,8]. In this case, our patient was seemed as hyperkalemia with low Estimated Glomerular Filtration Rate (eGFR) that was caused by acute kidney injury, and on beta-blocker medication but not in hypotensive shock state.

**Discussion**

Hyperkalemia is a dangerous electrolyte disorder that can lead to serious hemodynamic and neurologic complications. When serum potassium levels exceeding 6.5 mEq/L can cause respiratory paralysis or cardiac arrest. In general, hyperkalemia is seen when the increased potassium intake, decreased potassium excretion, or a shift of potassium from the intracellular to the extracellular space. Serum potassium more than 7.0 mEq/L is associated with abnormal cardiac electrical conduction and bradyarrhythmia with prolonged QRS interval, bizarre QRS morphology, high-grade AV block, slow junctional and ventricular arrhythmias, any kind of conduction block such as bundle branch blocks and fascicular blocks [4]. Sinus bradycardia or slow Atrial Fibrillation (AF) and development of a sine wave appearance (a pre-terminal rhythm) may also be seen in the electrocardiographic findings [5]. In cardiac cellular electrophysiology, higher serum potassium is usually seen as a flattening of the part of the action potential due to the reduction of cardiac pacemaker action potential in the concentration gradient (outflow) of potassium in repolarization state that leads to reduced heart rate [6].

If patients are found to be with bradycardiac, clinicians and medics should not miss life threatening hyperkalemic bradyarrhythmia due to electrolytes imbalance that may cause profound bradycardia or with different forms of heart block. The clue to the correct diagnosis is the broad QRS complex with absence of P waves. Hyperkalaemic related second and third degree Atrioventricular (AV) block may be seen sometime but they are uncommon because the P wave usually disappears before such advanced AV block occurs. If the ECG is available before the serum potassium and is consistent with life threatening hyperkalaemia, then it would seem sensible to give calcium glucuronate speculatively while waiting for the biochemistry results. In this case, our patient was seemed as hyperkalemia with low Estimated Glomerular Filtration Rate (eGFR) that was caused by acute kidney injury, and on beta-blocker medication but not in hypotensive shock state.

**Conclusion**

Hyperkalemic related bradyarrhythmia is not uncommon cardiac conduction disorder. Clinicians should be knowledgeable about the electrocardiogram changes and manifestations of electrolyte imbalance to provide effective initial management for hyperkalemia induced bradyarrhythmia in emergency care.
